I've decided to use Python as a programming language and as a data structure a HashTable. My HashTable is implemented using a list of deques from the collections library. The deque (Doubly Ended Queue) is extremely cool since it's a double sided queue which has **O(1)** time complexity for append and pop operations on either end. By using deques, I don't have to bother with resizes and collisions. As a hash function, I compute the sum of the ascii codes of the characters.
